

Indexing:

- provide speedy access to tables rows by storing sorted values of specified columns
- useful for select operation but costly on update, insert and delete operation

Guideline:

1. Don't use index for small tables , full table scan is fine for small tables
2. Create primary keys for all tables
3. For OLTP (Online Transaction Processing System), don't use excessive indexing
4. use index only if you need to access no more than 4 or 5 percent of the data in a table
5. index the column that are involved in where, having , join clause

Index are created

automatically on:

- primary key creation
- unique key creation

Manually:

- create index statement
- create table statement

Types of index:

unique and non-unique index

- better to use unique constraints rather than creating index

explicitly

primary and secondary index

composite index

- index having more than 2 columns
